

The Impact of Time Separation on Coordination in Global Software Teams: a Conceptual Foundation

Research Section

Avenue, N.W. Washington, D.C. 20016-8044, USA

While there has been much research on the study of global virtual teams and global software teams, there has been practically no research on the nuances of time separation. We present three converging perspectives on this topic: (a) a view from practices and tactics of global teams; (b) a theoretical view from coordination theories; and (c) a view from our prior research in which we modeled coordination costs for time-separated dyads. Practice suggests that time separation arises not only from time-zone differences but also from factors such as nonoverlapping weekend days and holidays, shifts, and different working schedules. It also suggests that teams employ various coping tactics when faced with time separation – synchronous, asynchronous, and education. Theory suggests that communication is necessary to coordinate and that effectiveness of communication is hampered, both in quality and timeliness, when teams are separated by time. Our model, based on coordination theory, suggests that coordination costs contain four main components – communication, clarification, delay, and rework – and that the various aspects of time-separated work have different effects on each of these components. Our convergent view from these three perspectives shows that distance separation is symmetric – i.e. distance (A,B) = distance (B,A) – while time separation is asymmetric, which affects the planning of team interactions; that the timing of activities matters in time-separated contexts but not in contexts with only distance separation; and that *vulnerability costs* (i.e. resolving misunderstandings and rework) increase with time separation. KEY WORDS: global software teams; global software development; geographically dispersed teams; coordination costs; time separation

1. INTRODUCTION

Coordination in different-time contexts (time zones, holiday differences) is difficult because of lean

communication media, difficulties in resolving unclear messages, reduced opportunities for spontaneous interaction, and lack of contextual reference. Fundamentally, time differences tend to increase *coordination costs*. Yet, despite these costs, team work is increasingly carried out globally. There are a number of reasons for this increase. One reason is that since software products are digital, their transportation costs are very low and delivery time is effectively zero. Also, *production*

1 costs in many ('offshore') distant locations are low.
2 In addition, geographic dispersion enables companies to access specialized software talent and technical resources (Carmel 1999).

5 These cost-benefit trade-offs – of higher *coordination costs* and lower *production costs* – are important, complex, and not fully understood. As a result, this topic has interested researchers and practitioners studying coordination in distributed software teams (Carmel 1999, Herbsleb and Grinter 1999, Herbsleb *et al.* 2001, Espinosa *et al.* 2002) and geographically dispersed teams in general (Van den Bulte and Moenaert 1998, Olson and Olson 2000, Cramton 2001, McDonough *et al.* 2001, Armstrong and Cole 2002, Kiesler and Cummings 2002). Research focused on time differences has only begun to appear recently (Klein and Kleinhanns 2003, van Fenema and Qureshi 2004).

19 There are a number of difficulties associated with the study of global software teams, particularly when trying to understand the effect of geographic dispersion. For example, many studies look at geographic dispersion as a binary attribute – i.e. teams are either colocated or geographically distributed. However, teams may operate in a variety of geographic dispersion configurations (O'Leary 2001, O'Leary and Cummings 2002) (e.g. two sites: one central site with several small satellite sites, several sites with evenly distributed effort, etc.).

31 On the basis of the configuration permutations of O'Leary and Cummings (O'Leary and Cummings 2002), we discuss three cases of increasingly complicated time adjustments, illustrated in Figure 1. First, two sites working in different time zones separated by a few hours (e.g. England–Germany, New York–Chicago) can mutually adjust their work schedules such that they maximize work-time overlap. Second, one hub site (e.g. London) with many developers collaborating with a number of developers in multiple satellite locations spread throughout multiple time zones (e.g. New York and Bangkok). Thus, developers in the satellite locations can adjust their work hours to maximize overlapping work hours with the central hub location. Third, and most difficult, is when many developers are widely scattered across multiple time zones, providing very little work-time overlap in which developers can interact simultaneously.

50 Researchers have found that difficulties due to geographic dispersion often correlate with other

team boundaries like functional identity, differences in local context and local culture, etc. (Orlikowski 2002, Watson-Manheim *et al.* 2002, Espinosa *et al.* •2003). More specifically, we emphasize that when distributed teams are also separated by time (e.g. time zones, differences in work cycles, shift work, etc.) it becomes difficult to tease out the true effects of geographic dispersion. Distance and time effects are often confounded in global software team studies because many geographically dispersed teams are often also separated by time zones.

In this paper, we discuss important conceptual issues and analyze the implications of time separation from three perspectives. We first discuss time-separation issues from a practical perspective. We then discuss similar issues from a theoretical perspective. Because of the paucity of research on the effects of time separation, we bring to bear theories related to coordination in general and the research literature on coordination in software development. We then analyze the implications of time separation from these theoretical perspectives. Finally, we present our coordination model to better understand the effects of time separation on coordination in software tasks. We conclude with a discussion section where we identify overarching issues derived from these three perspectives, which affect research and practice in time-separated contexts, and then offer suggestions for further research.

2. TIME-SEPARATION ISSUES: A VIEW FROM PRACTICE

In this section, we summarize tactics (in Table 1) that we have found from interviews conducted for other studies of global software teams (Carmel 1999, Espinosa 2002) and through exploratory interviews and discussions we have conducted recently with software professionals involved in time-separated collaborations. The interviews were taped and transcribed in each of the studies. We analyzed the data by identifying incidents in which interviewees brought up time-separation issues. Our method is consistent, to some extent, with the Critical Incidents method (Chell 1998), but we departed from it in some respects: the interview questionnaires were semistructured and were designed for other studies; formal interview

2.1. Practices Used by Virtual Teams to Overcome Time Separation

14 In overcoming time-zone differences, we found
 15 three principal solution tactics, which we summa-
 16 rize in Table 1 and discuss in more detail below:

- *Asynchronous*: Teams instill better practices in their nonoverlapping work times to compensate for the lack of common work hours.
- *Synchronous*: Teams plan for the existing synchronous overlap times and/or enlarge the windows of synchronous (overlapping) times.
- *Education*: Individuals in the teams become more effective across time differences, with better awareness and better information.

Teams use a number of *asynchronous* tactics to cope with time separation. First, and most obvious, they make better use of asynchronous technologies, such as electronic mail, voice mail, and use of various shared databases and other repositories (groupware, knowledge management, team intranets and

Table 1. Tactics to overcome time separation

Category	Tactic
Asynchronous	<ul style="list-style-type: none"> • Use of asynchronous technologies • Formalization of activities • Bunch-and-batch • Break the e-mail chain
Synchronous	<ul style="list-style-type: none"> • Shift dialogue to overlap time and independent work to asynchronous time • Expand overlap window by working longer • Expand overlap window by shifting work hours • Expand overlap window by always being available • Create liaison roles with adjusted hours that expand overlap window of only those individuals rather than the entire team
Education	<ul style="list-style-type: none"> • Build awareness • Create easy access to current time, calendar, and holiday schedule of distant actor(s)

AO4

1 web sites, discussion areas, etc.). Domains like
2 software development also have specialized collabora-
3 tion tools designed to help team members work
4 effectively in an asynchronous way (e.g. configura-
5 tion management systems, error logs). For example,
6 in one of our previous studies, we found that a
7 substantial amount of coordination in distributed
8 software teams was accomplished through a configu-
9 ration management system (Espinosa *et al.* 2002).
10 Such systems are generally used to help developers
11 manage simultaneous software changes, but many
12 developers in that study used the comments field to
13 exchange asynchronous notes and messages about
14 the code. This has also been observed in other stud-
15 ies (Grinter 2000). Effective time-separated teams
16 also learn to formalize (i.e. program, structure)
17 activities and messages so that they convey informa-
18 tion in a more effective manner, thus reducing the
19 need for further clarification communication. They
20 also learn to organize their workdays so that they
21 bunch-and-batch their work in order to maximize
22 completion, before the work is delivered to distant
23 sites. Finally, effective individuals learn to 'break
24 the e-mail chain'. The e-mail chain begins when
25 one actor initiates a message, the receiver does not
26 understand it fully and asks for clarification, the
27 sender attempts to clarify, the receiver misinterprets
28 again, and so on. Meanwhile, an entire week has

gone by. Therefore, experienced individuals stop
this chain early 'by picking up the phone' and clari-
fying the message through a richer communication
medium.

Synchronous tactics address time separation more
directly. First, if there is some time overlap,
teams synchronize their dialogue time so as to
maximize synchronous exchange (e.g. telephone,
instant messaging, videoconferencing). Thus, work
that can be done independently is conducted during
nonoverlap time so that overlap time can be devoted
to meetings, telephone conversations, adjustments,
problem resolutions, and other actions better done
synchronously. There are a number of variations
on this tactic noted in the field data of Klein
and Kleinhanns (2003): experienced actors learn to
package their information so that it can be better
absorbed by the distant actors, more work is shifted
to nonoverlap time so that synchronous meetings
become more productive, and questions for overlap
time are prepared ahead of time. Second, and most
familiar, teams tend to enlarge the overlap period by
shifting and expanding work hours. For example,
European staff may start late and work late so
as to have greater overlap with their American
counterparts. Conversely, the American staff may
start early so as to expand the overlap time with
their European counterparts. Japanese companies
are notorious for working late hours, thus enlarging
the overlap window with their counterparts. We
heard recently from a Chinese software company
developing software for a Japanese client (China
is one hour behind Japan) that because Japanese
developers tend to work late, there is no noticeable
time difference.

Some software organizations also create liaison
roles to help team members interact across sites. In
one of our previous studies involving a software
team with members in the United Kingdom,
Germany and India, we found that a number
of Indian software engineers were trained in
the UK and German sites for a few months to
familiarize themselves with team members and the
work context in those sites and then worked as
liaison engineers (Espinosa 2002). Once trained,
these liaison engineers would go back to India
and would serve as points of contact for the UK
and German developers. Liaison engineers would
often adjust their work schedules to increase their
window of work-time overlap with their British and
German counterparts. In practice, this time-window

1 expansion is practiced only by some of the virtual
2 team members – particularly managers and team
3 leaders.

4 Time *education* tactics involve learning how to
5 work effectively under time-separated conditions.
6 Less-experienced team members need to be made
7 aware of time-separation issues. They are not used
8 to thinking about their counterparts being gone
9 for the day while they work. They are not used
10 to computing the direction of the time difference.
11 Thus, various awareness tactics are important. (e.g.
12 the distant team member reminds her counterpart
13 that the scheduled meeting is set for 2 PM local time,
14 and members remind their distant teammates about
15 shift to ‘daylight savings time’, which is at different
16 times in different countries). A simple tactic is to
17 post hours and time differences on the common
18 web site.

19
20

21 2.2. Time Separation is Disruptive

22
23 One often hears that individuals in global software
24 teams spend many evenings, nights, and early
25 mornings in telephone conversations across the
26 oceans. Overlap-window expansion, which we
27 noted above, is a disruption of one’s personal time
28 and further dilutes the boundaries between work
29 and home life. Now that wireless communication
30 devices are ubiquitous, key individuals are always
31 reachable. Balanced teams try to shift the burden
32 of late-night (or early-morning) conference calls in
33 order to soften the pain of disruption. But, we have
34 heard of many cases where the dominant/hub site
35 dictates meeting times convenient to their normal
36 workday, never adjusting for the sake of the distant
37 participants. We note a similar litany of complaints
38 about time differences in the work of Klein and
39 Kleinhanns (2003) and van Fenema and Qureshi
40 (2004). Not all individuals are accommodating
41 on overlap windows. We heard a story at one
42 major California-based technology firm working on
43 urgent software fixes in a global collaboration, in
44 which

45

46 ‘the British technical experts liked waking
47 up early in the day to work, while their
48 California counterparts liked coming into the
49 office late and working late (California is
50 8 hours behind Britain). Thus, they had no
51 synchronous overlap window and relied on

one e-mail batch per day, which really slowed 52
down the work.’ 53

54

55 2.3. Time Separation is more than just Time-zone 56 Differences 57

58 While time-zone differences are the most recogniz-
59 able element of time separation in work coordina-
60 tion, other factors increase coordination difficulty:
61 work hours, lunch breaks, weekend times, and hol-
62 iday times. These are summarized in Table 2. We
63 discuss each of these in turn.

64 Time-zone differences, even small ones, can
65 create substantial problems if the work-time overlap
66 between the two sites is not synchronized. For
67 example, a study on coordination in global software
68 teams found that a one-hour time-zone difference
69 between two sites substantially affected the team’s
70 ability to communicate interactively because it
71 reduced their overlapping time by four hours – one
72 hour at the beginning of the day, one hour at the
73 end of the day, and one hour during each site’s
74 lunch break (Grinter *et al.* 1999). Work hours may
75 also vary by country. While Americans are used to a
76 standard day of roughly nine-to-five, office workers
77 in Spain start working later in the day, have longer
78 lunch breaks, and finish their workday often much
79 later than 7 p.m.

80 Weekend times may also vary. While much of
81 the world has a weekend on Saturday and Sunday,
82 this is not universal. In Arab countries, Friday is
83 not a workday. The weekend in Israel is Friday and
84 Saturday, which creates a long ‘blackout period’
85 when working with collaborators in the United
86 States – Americans come to work on Thursday
87 morning when the Israelis have already left for
88 the weekend. The patchwork of national holidays
89 is also bewildering. One American technology firm
90 we interviewed had staff in more than a dozen
91 European nations and because of different national
92 holidays, there were only 50 regular workdays in

93

Table 2. Types of time differences 94

1 common in any given year for the purpose of
2 scheduling synchronous meetings (e.g. the entire
3 month of August is not usable for several European
4 nations).

5
6
7 **2.4. Configuring Global Software Teams for
8 Time Separation**

9 We note two global team configurations that
10 specifically address time separation. We emphasize
11 that, unlike the practices described earlier, they
12 are not tactical in nature. The first purposefully
13 positions teams in nonoverlapping time zones,
14 while the second purposefully positions teams in
15 overlapping time zones. The first is an approach that
16 has received a great deal of attention: 'Follow-the-
17 sun' work, also known as 'round-the-clock' software
18 development (Carmel 1999), which takes advantage
19 of time-zone differences to speed up project work.
20 For example, a team in Eastern United States can
21 hand off work at the end of their day to team
22 members in India or China, who can continue the
23 task after the US team members go to sleep. The
24 appeal of this strategy is enormous, for, if it can be
25 coordinated properly, it can reduce project duration
26 by a factor of two for the two sites mentioned above,
27 at least in theory. Clearly, coordination in *follow-the-
28 sun* must be effective, which is why the authors are
29 not aware of any successful cases of this approach on
30 a regular basis. Many teams have noted occasional
31 time reduction using the *follow-the-sun* approach
32 (e.g. once a week). But, continuous *follow-the-sun* is
33 too difficult for software teams to conduct because
34 of the high dependencies implicit in the concept
35 and the need for near-perfect communication and
36 coordination. However, we have found *follow-the-
37 sun* to be effective for low granularity tasks such
38 as bug-fixing or call-center activity (e.g. technical
39 support).

40
41 The second configuration approach is the pur-
42 poseful positioning of a companion site within
43 closely overlapping time zones. Gumpert (2004)
44 describes a case of a software start-up in Austin,
45 Texas that started collaborating with an offshore
46 partner in India (whose time zone is 11.5 hours
47 ahead). The principals at the firm found that coordi-
48 nation with India was too difficult because of time
49 differences, and they moved to an offshore partner-
50 ship in Columbia – only one time zone away from
51 Texas.

3. COORDINATION IN SOFTWARE 52
DEVELOPMENT: A VIEW FROM A 53
THEORETICAL PERSPECTIVE 54
55

As we noted, there has been no theoretical research 56
specifically on the impact of time differences. 57
Thus, we turn to coordination theories to inform 58
the deeper understanding of the impact of time 59
differences. Consistent with coordination theory 60
research, we define coordination as the manage- 61
ment of dependencies among task activities to 62
achieve a goal (Malone and Crowston 1990, 1994). 63
A few important principles deriving from this def- 64
inition are worth noting. First, if task activities can 65
be carried out independently, then there is no need 66
to coordinate. Conversely, more complex tasks like 67
software development have substantial dependen- 68
cies that need to be managed, thus the need for 69
coordination. For example, when many software 70
individuals and teams are working in parallel to 71
build a single software product, different software 72
parts need to interoperate properly and tasks (e.g. 73
coding) need to be completed on schedule to avoid 74
delaying other tasks (e.g. testing). Second, when 75
task activities contain tightly coupled dependen- 76
cies, the individual decisions and actions of team 77
members involved in a task become mutually con- 78
straining (Herbsleb and Mockus 2003). One team 79
member's work on a task may need to stop until 80
another team member's work is completed. Finally, 81
if a task is analyzed with a fine-grained level of 82
detail such that the dependencies and mutual con- 83
straints among task activities are well understood, 84
one can begin to identify different coordination 85
mechanisms that can be employed to manage these 86
dependencies effectively. 87

Dependencies in a task can be pooled (i.e. two 88
tasks depend on the same resource pool), sequential 89
(i.e. task A cannot proceed until task B is completed), 90
or reciprocal (i.e. tasks A and B are interdependent) 91
(Thompson 1967). For example, one team member 92
may be working on a task (e.g. software coding) and 93
may reach a point at which the work needs to be 94
handed over to another team member who needs 95
to perform another task (e.g. testing) such that the 96
first member's work on this task cannot continue 97
until the second member's task is finished. This 98
sequential dependency among two members needs 99
to be effectively managed to achieve coordination. 100

The organizational research literature suggests 101
that team members coordinate nonroutine aspects 102

AQ5

1 of their work through communication (March and
2 Simon 1958, Thompson 1967, VanDeVen *et al.* 1976).
3 When team members are separated by geographic
4 distance and/or time, their ability to communi-
5 cate interactively and on a timely basis is ham-
6 pered, thus negatively affecting team members'
7 ability to manage dependencies among their task
8 activities. Thus, while teams also use other coor-
9 dination mechanisms (e.g. plans, tools), we focus
10 our discussion on coordination by communication
11 because software development is a complex task
12 with substantial nonroutine, interdependent activi-
13 ties, which require a fair amount of communication
14 to coordinate. In addition, communication is an
15 obvious way for team members to generate other
16 coordination processes (Malone and Simon 1994).
17 Furthermore, communication is important in time-
18 separated contexts because the frequency (Allen
19 1977, Kiesler and Cummings 2002) and (Waller
20 1999, Gittell 2001) timeliness of communication can
21 be adversely affected when team members are not
22 in close proximity.

23 On the other hand, a recent study found evi-
24 dence that software teams working in the same
25 room had significantly higher productivity than
26 other teams that were not colocated (Teasley *et al.*
27 2002). They concluded that their productivity was
28 greater because colocation in the same room bol-
29 stered collaboration by facilitating interactive con-
30 tinuous communication and awareness. In contrast,
31 one may conclude that when team members are
32 separated by distance, these benefits disappear.
33 Furthermore, if they are also separated by time
34 differences, then both continuous communication
35 and awareness of team members will be hampered
36 even more, thus causing further delays because
37 of coordination breakdowns and rework, making it
38 particularly difficult to close open issues. As another
39 study found, spanning multiple time zones can
40 affect the rhythm of a team's work, creating unex-
41 pected faultiness (Espinosa *et al.* 2003), more so if
42 teams are separated by additional boundaries (e.g.
43 culture, function, language) (Lau and Murnighan
44 1998).

47 4. OUR COORDINATION MODEL: A VIEW 48 FROM A MATHEMATICAL PERSPECTIVE

49 In this section, we describe our model of *coordination*
50 *costs* due to time differences in dispersed software

51 teams. Our model is more fully described and 52
53 validated with simulated data elsewhere (Espinosa 53
54 and Carmel 2004). While our focus is on global 54
55 software teams, the model is generic, and can 55
56 apply to any type of virtual knowledge team. Our 56
57 model is derived following Malone and Crowston's 57
58 coordination theory, (Malone and Crowston 1990, 58
59 Malone and Crowston 1994) in which coordination 59
60 is viewed as the management of dependencies 60
61 among task activities, and Malone's formulation 61
62 of coordination costs in organizations and markets 62
63 (Malone 1987). While coordination theory does 63
64 not specifically address issues of distance and 64
65 time separation, we incorporate distance and time 65
66 separation in our analysis by evaluating how the 66
67 total cost of carrying out a task is influenced by the 67
68 cost and effectiveness of different communication 68
69 mechanisms in various collaboration modes (i.e. 69
70 colocated and separated by distance and/or time) 70
71 and by delays caused by time separation. 71

72 We begin by delineating our assumptions about 72
73 distributed coordination and communication. First, 73
74 we make no distinctions between the granularities 74
75 of a task request encapsulated in a message. A 75
76 task can be a large one, perhaps requiring several 76
77 days of effort, or it can be a very small one, 77
78 such as a yes-no answer. Next, we make an 78
79 assumption about media choice. If a situation arises 79
80 in one site that requires interaction with another 80
81 site during their off-work hours, being unable to 81
82 pick up the phone and call other members can 82
83 slow down a group's progress. The choices for 83
84 a team member in such a situation are to either 84
85 send a request asynchronously (e.g. e-mail) or 85
86 wait until work hours overlap again to make the 86
87 request synchronously (e.g. phone call). Requests 87
88 are often not clear, requiring additional clarification 88
89 communication, further delaying the whole process. 89
90 When team members are working face-to-face, the 90
91 clarification may be nearly instantaneous. Even 91
92 when members are distant, but in same-time 92
93 zones, clarifications can be made very quickly 93
94 through phone calls, •IM, or videoconference. 94

95 However, when team members are separated by 95
96 time, the need to clarify messages will introduce 96
97 further delay, unless this happens during work- 97
98 overlapping hours. 98

99 Our model begins by looking at a single collab- 99
100 oration act between two actors – a task *Requestor* 100
101 who makes a request to another actor who is the 101
102 task *Producer* because of a workflow dependency, 102

AQ6

AQ7

1 i.e. the work of the *Requestor* cannot continue until
 2 the work of the *Producer* is finished. •For this to
 3 happen, the *Requestor* must communicate the task
 4 requirements to the *Producer*, and the *Producer* must
 5 communicate an acknowledgement to the *Requestor*
 6 when the dependent task is completed (Malone and
 7 Crowston 1994, Malone *et al.* 1999). As illustrated
 8 in Figure 2, team members may be interacting in
 9 any of four possible (2 × 2) collaboration modes,
 10 depending on whether the dyad is separated by
 11 distance and/or by time: face-to-face, separated by
 12 distance only, separated by time only, or separated
 13 by distance and time (Bullen and Bennett 1993).

14 The coordination issues of two such actors, who
 15 are separated by distance, can be substantial. Our
 16 model shows that these issues compound even
 17 further with time separation. For example, one
 18 central aspect of our model is that the overlap
 19 in work hours between any two members who
 20 collaborate can take place either at the beginning or
 21 at the end of one’s workday. The synchronous or
 22 asynchronous solutions to time separation will have
 23 to be worked out differently, depending on when
 24 the work-time overlap occurs in one’s workday.

25 In our model, actors need to communicate, and
 26 this communication is costly and time separation
 27 introduces asymmetries. An asymmetry takes place
 28 when work overlap occurs at the beginning of one
 29 site’s workday and at the end of the other site’s
 30 workday (there is no asymmetry when work times
 31 fully overlap). Because of this asymmetric property
 32 of time separation, we argue that the effect of time
 33 separation on global software team coordination
 34 can be modeled and studied by analyzing timing
 35 issues (e.g. when interactions occur, task duration
 36 times, and amount of overlap in work hours) and
 37 then by evaluating how they affect *production costs*
 38 (i.e. the cost of carrying out individual tasks) and

Time	Different	New York - India (10.5 time zones away)	Co-located shift work
	Same	Chicago - Mexico City (0 time zones away)	Same office, same work hours
		Different	Same
		Place	

51 Figure 2. Time by place matrix

52 *coordination costs* (i.e. the cost of managing the
 53 dependencies between individual tasks).

54 This breakdown of total costs into production
 55 and *coordination costs* is similar to the breakdown
 56 suggested by Malone in his theoretical modeling of
 57 coordination in organizations and markets (Malone
 58 1987), which has been widely used in theoretical
 59 and simulation research involving coordination
 60 (Koushik and Mookerjee 1995, Carley and Lin 1997,
 61 Jehiel 1999). However, for the purposes of study-
 62 ing the effects of time separation, we find that it is
 63 more useful to further decompose *coordination costs*
 64 into: (a) *communication costs* – the cost of maintain-
 65 ing communication links and the cost of sending
 66 and receiving messages; (b) *delay costs* – the cost of
 67 delays caused by the dependency requiring com-
 68 munication; (c) *clarification costs* – the cost of further
 69 communication required to repair miscommuni-
 70 cation; and (d) *rework costs* – the cost of further
 71 production necessary for work that was completed
 72 before the miscommunication was discovered (see
 73 Table 3). Following Malone’s terminology, we refer
 74 to clarification plus *rework costs* as *vulnerability costs*
 75 because these costs originated as a result of mis-
 76 communication. *Delay costs*, on the other hand, are
 77 affected by the latency inherent in the communica-
 78 tion media and by working-time differences.

79 While our model follows Malone’s model, we
 80 make some adjustments to take into account delays
 81 resulting from distance separation or time zones
 82 differences. First, we specifically model time and

85 Table 3. Cost components

Cost components	Definition
Production	The costs of carrying out the task
Communication	The costs of maintaining communication links and sending and receiving messages.
Delay	The costs incurred because one actor is waiting for another to begin their work day.
Clarification	The additional cost of communication and delay due to prior miscommunication that resulted from the need to communicate asynchronously.
Rework	The additional costs of production due to miscommunication that resulted from the need to communicate asynchronously.

1 distance separation between actors. Second, Mal- 52
 2 one's model analyzes different coordination struc- 53
 3 tures for a set of actors, while our model employs 54
 4 only two actors, who need to carry out a task with 55
 5 a tightly coupled workflow dependency, who coord- 56
 6 inate via communication. Finally, Malone's model 57
 7 assumes that actors employ their production capac- 58
 8 ities optimally, but we do not need to make this 59
 9 assumption because there are only two actors in 60
 10 our model. 61

11 Malone defines *production costs* as the average 62
 12 delay in processing the task, but since Malone's 63
 13 model does not incorporate time delays due to time 64
 14 separation, his *production costs* amount to the time 65
 15 it takes to carry out the task, which is consistent 66
 16 with our definition of *production costs*. Malone 67
 17 defines *coordination costs* on the basis of the cost 68
 18 of maintaining communication links and the cost of 69
 19 sending messages among nodes in the coordination 70
 20 structure. However, in Malone's model, messages 71
 21 arrive instantly. Our definition of *coordination costs* is 72
 22 similar to Malone's but we also incorporate the time 73
 23 delay introduced due to time separation (e.g. one 74
 24 member may send a task request during the other 75
 25 member's off-work hours). Finally, Malone defines 76
 26 *vulnerability costs* as those due to failures of those 77
 27 involved in the task, leading to task reassignments. 78
 28 Because our model involves only one dyad, there 79
 29 is no reassignment. Instead, failures lead to further 80
 30 communication and coordination to clarify things 81
 31 and, possibly, to reprocess part of the task (i.e. 82
 32 rework). A message can be unclear, with some 83
 33 probability. Unclear messages can lead to either: 84
 34 (1) rework, resulting in additional *production costs* 85
 35 for a portion of the work with further delays; and/or 86
 36 (2) a simple request for clarification, resulting in 87
 37 additional *coordination costs*. We now describe the 88
 38 mathematical formulation of the main components 89
 39 of our model. All cost variables are specified in 90
 40 financial terms and all time variables are specified 91
 41 as proportions of a workday (e.g. 0.5 = half of a 92
 42 workday, 3 = two workdays). 93

43 *Production Costs (Pc)* in our model are simply the 94
 44 *Producer's* daily cost of carrying out tasks, and it can 95
 45 be specified as 96

$$Pc = \lambda CpTt \quad (1)$$

47 Where λ is the daily frequency of task arrivals, Cp is 97
 48 the daily production cost rate for the *Producer*, and 98
 49 Tt is the time it takes the *Producer* to complete the 99
 50 task. This cost component only involves individual 100

production time and costs incurred by the *Producer* 52
 and it is unaffected by time or distance separation. 53

Communication Costs (Cc) for two actors include 54
 the daily cost of maintaining a communication link 55
 (Cl), plus the daily cost of sending individual single 56
 messages (Cm). The cost of maintaining a face-to- 57
 face link and the cost of face-to-face communication 58
 are assumed to be negligible for colocated teams, 59
 compared to other *communication costs*. The cost of 60
 maintaining a synchronous and an asynchronous 61
 communication link are (Cl_s) and (Cl_a), and the cost 62
 of sending a synchronous and an asynchronous 63
 message are (Cm_s) and (Cm_a), respectively. Thus, 64
 the daily *communication costs* can be specified as 65

$$Cc = Cl + 2\lambda Cm \quad (2)$$

66 that is, a task requires a message to request 67
 the task and a message to acknowledge comple- 68
 tion of the task. Depending on whether the 69
Requestor and *Producer* communicate synchronously 70
 or asynchronously, there are several permutations 71
 of Equation (2). For example, if both members com- 72
 municate synchronously, the *communication costs* 73
 would be $Cl + 2\lambda Cm_s$, but if one communicates 74
 synchronously and the other asynchronously, the 75
 cost would be $Cl + Cl_a + \lambda(Cm_s + Cm_a)$. 76
 77

Delay Costs (Dc) in our model are measured from 79
 the perspective of the task *Requestor*, because this 80
 is the actor who has a dependency, whose work 81
 is delayed while the *Producer* completes the task. 82
 Thus, daily *delay costs* can be specified as 83

$$Dc = \lambda TdCd \quad (3)$$

84 Td is the delay experienced by the task *Requestor* 85
 while the *Producer* completes the task and Cd is 86
 the daily rate of cost delay for the task *Requestor*. 87
 One interesting property of this cost component 88
 is that if the *Producer* carries out the task during 89
 the *Requestor's* off hours, Td is zero, which is the 90
 motivator for software work organized in *follow-the-* 91
sun arrangements. On the other hand, if the *Producer* 92
 does all the work during overlapping work hours, 93
 Td is identical to the time it takes to carry out the 94
 task Tt . Thus, the degree of time separation or work-time 95
 overlap for a dyad will have a substantial impact 96
 on *delay costs*. 97
 98

Clarification Costs (Cf) will be incurred when task- 100
 request messages are not clear and the task *Requestor* 101
 and task *Producer* need to communicate again 102

1 to resolve the misunderstanding, thus incurring
2 further communication and delay costs. If there is a
3 probability P_u that a task-request message will be
4 unclear, then C_f can be specified as

$$5 \quad C_f = P_u(C_c + D_c) \quad (4)$$

6
7
8 *Rework Costs* (R_c) will be incurred if the need for
9 clarification occurs after the *Producer* has started to
10 work on the task and some of the software work
11 needs to be redone. If there is a probability P_r that a
12 given unclear message will lead to rework and that
13 the proportion of the total task that needs rework is
14 R_w , then R_c can be specified as:

$$15 \quad R_c = P_u P_r R_w P_c \quad (5)$$

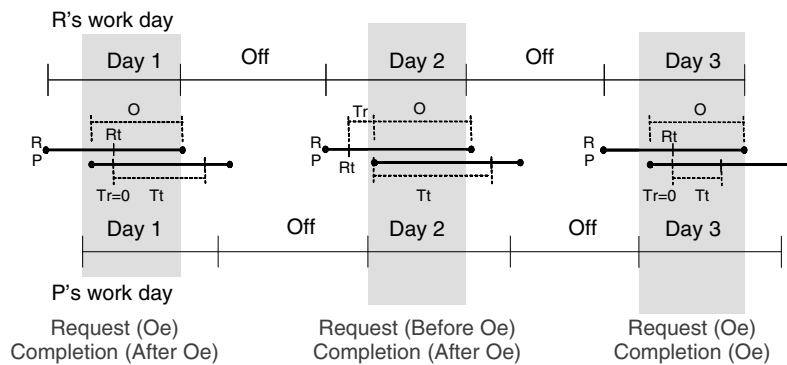

16
17
18 Clarification and *rework costs* are equivalent to
19 what Malone calls 'vulnerability' costs. In other
20 words, if all goes well, the cost incurred in car-
21 rying out the task equals P_c , C_c , and D_c . If these
22 were the only costs incurred, then *follow-the-sun* and
23 *round-the-clock* programming arrangements would
24 be ideal because they would save substantial *delay*
25 *costs* by maximizing the amount of task production
26 that takes place during the *Requestor's* off hours.
27 However, the problem with these work arrange-
28 ments surfaces when vulnerabilities materialize,
29 requiring further communication to clarify issues
30 and possible rework. An important aspect of these
31 two cost components is that they are both affected
32 by the quality and richness of the communication
33 medium used to communicate. In our model, the
34 value of P_u is dependent on the particular medium
35 used. For example, P_u for face-to-face communi-
36 cation is very low because team members have
37 a very rich communication medium that allows
38 them to use contextual references and nonverbal
39 cues. P_u is likely to increase as teams move to
40 leaner communication media like videoconference,
41 voiceconference and electronic mail. P_u will also
42 increase as global team members span more bound-
43 aries (e.g. cultural, functional, language), making it
44 more difficult for members to communicate clearly
45 (Watson-Manheim *et al.* 2002, Espinosa *et al.* 2003).

46 If, for example, a distributed team communicates
47 via inexpensive voiceconference, then the lean
48 communication media will make it more difficult
49 to convey ideas clearly. On the other hand, if the
50 team uses videoconference with supporting tools
51 (e.g. a whiteboard), the need to clarify messages

will be reduced. These two cost components will
also be affected by time separation because this may
introduce longer delays and may force a team to use
asynchronous communication tools at times when
such communication media may not be the most
effective for the task at hand. As Media Richness
theory suggests, lean communication media (e.g.
electronic mail) may not be the most appropriate
form of communication for equivocal tasks that
contain more uncertainties (Dennis and Kinney
1998). We argue that it is these *vulnerability costs*
stemming from clarification and *rework costs* that
make work arrangements like *follow-the-sun* so
difficult for many software tasks.

In sum, our model is parsimonious and it involves
individual *production costs* (P_c) necessary to carry
out individual software development task activities
and a coordination cost (C_o) necessary to manage
the dependencies among different task activities.
These *coordination costs*, in turn, are composed of
communication costs (C_c), *delay costs* (D_c), *clarifica-*
tion costs (C_f), and *rework costs* (R_c). Nevertheless,
the specific application of these formulas will vary
substantially in complexity depending on the pat-
tern and timing of team members' synchronous and
asynchronous interaction, as illustrated in Figure 3.
One of the key issues that our model uncovers, as
depicted in this figure, is that *coordination costs* are
sensitive to the time at which a request is initiated
and the time at which that request is responded to.
A request can be initiated during overlap and be
responded to after overlap, it can be launched before
overlap and responded to after overlap, or it can be
initiated and responded to within the overlap.

Also, while our simple model considers only
two actors, a task *Requestor* and a task *Producer*,
it can be readily extended to larger teams in
multiple work configurations consisting of many
task *Requestors* and *Producers*. However, as we
incorporate various synchronous and asynchronous
interaction modes into larger teams, the complexity
of the model grows exponentially. We also note
that our model is consistent with other coordination
models in the global software team literature. For
example, one model suggests that actors need to
communicate to make decisions that are mutually
constraining and that this communication is affected
by time separation (Herbsleb and Mockus 2003).
Another model suggests that communication is
the main mechanism through which informational
coordination is achieved (Chaudhury *et al.* 1996).

AQ1

Figure 3. Graphical depiction of two actors with time-zone separation •Overlap time is depicted in yellow. R is the Requestor, P is the Producer. In Day 1, the request is made during the overlap period but the task is completed after overlapping hours; in Day 2, the request is made before overlapping hours and the task is completed after overlapping hours; in Day 3, the task is requested and completed during overlapping hours

1 **4.1. Applications of Our Model**

2 One of our main goals when we developed our
 3 model was to keep it as simple as possible,
 4 while retaining its explanatory power. The model
 5 involves a single collaboration act between two
 6 team members who have a sequential dependency,
 7 and it decomposes the total cost of carrying out this
 8 act into production and coordination. Coordination
 9 costs are further decomposed into four components:
 10 communication, delay, clarification, and rework
 11 costs. We argue that this model is very useful
 12 because it offers a fine level of granularity of
 13 coordination costs at the root of the collaboration
 14 process, which can help us understand coordination
 15 costs in more complex collaboration arrangements
 16 in which team members are separated by time.
 17 Parsimony is a widely accepted property for
 18 theoretical models (Rosenthal and Rosnow 1991),
 19 but it is particularly important for our model
 20 because things complicate rapidly as we add more
 21 members and time differences to the team. It is
 22 precisely this simplicity that makes our model
 23 useful to understand coordination costs in more
 24 complex team structures.

25 The power of the model resides in its ability to
 26 be adapted to more real conditions by changing
 27 parameters and by relaxing assumptions. These are
 28 some examples of possible expansions of the model:
 29 (a) •the presence of multiple synchronous and
 30 asynchronous communication tools can be modeled
 31 with a choice function based on the communication
 32 costs and expected communication quality payoff
 33 based on Pu ; (b) larger teams can be modeled using
 34

AQ8

network analytic methods in which each team 35
 member is represented as a network node with 36
 a particular Cp and Cd , and each collaborating dyad 37
 in the team is represented as a *Requestor-Producer* 38
 relationship; (c) different types of tasks can be 39
 modeled by manipulating the task duration Tt , the 40
 frequency of task request λ , the task equivocality 41
 (i.e. equivocal tasks are more uncertain, thus require 42
 more clarifications, thus a higher Pu), and the 43
 type of dependencies involved (i.e. sequential or 44
 reciprocal); and (d) multitasking can be represented 45
 by assigning priorities to tasks and additional 46
 delays to Td on the basis of these priorities. Table 4 47
 illustrates how different components of our model 48
 help us understand the effect of time separation on 49
 coordination costs in a number of important GSD 50
 (global software development) practices. 51

52
 53
 54 **5. DISCUSSION**

55 Our study has several limitations. First, while 56
 we draw from three perspectives – practice, theory, 57
 and modeling – to provide a unified view of 58
 the coordination challenges in time-separated contexts, 59
 we only describe our model briefly. We have 60
 described our model in more detail in another 61
 paper, but the model still needs further development 62
 and empirical validation. Our model is 63
 based on simplifying assumptions, which we plan 64
 to relax as we develop it further. For example, we 65
 made no distinctions between the granularities of 66
 a requested task. More complex tasks that contain 67
 many subtasks would need to be modeled with 68

Offshore Outsourcing (OO)

- Time-zone separation may be large or small
- 2 dyads (in simple case).
- Task dependency may be high or low.
- Companies outsource software development offshore because daily production cost rates C_p are low in low wage countries.
- But coordination costs can be high.
- Higher quality communication tools will improve the media richness, thus lowering P_U , which will increase communication costs but will also reduce clarification and rework costs.
- Delay costs are low if overlap is small and task requests are batched and sent shortly before the overlap – Td is small if work can be done while the requestor sleeps.
- In contrast, delay cost can be substantial if task request are made several hours before the overlap time.
- Delay costs are high in same-time contexts because the delay Td is equal to the task completion time Tt
- Costs are reduced with longer overlaps because Td is no longer dependent on Tt but on how long it takes to get the clarification response from the task producer.
- If the response does not arrive during the overlap period, the task producer has to wait a full day to get a response.
- Rework costs are higher when P_U increases.
- Rework costs are affected by the producer's daily cost of production C_p . So, rework costs in OO can be small if C_p is small, thus, the incentive to work with countries where labor rates are low.

Large-Scale Global Software Development (LGSd)

- Multiple dyads with many task producers with varying degrees of dependencies
- Time-zone separation may be large or small
- Large number of individual task producers in many locations, each with a different C_p .
- Task requestors and producers may be grouped in locations in a number of different configurations.
- Same as OO
- There are many task requestors with different C_d 's in multiple locations.
- Delay costs are lower with a distributed team configuration that maximizes dependencies within sites and minimizes dependencies between sites – i.e. low λ (e.g. coding in one site, testing in another; core development in one site, customization in another).
- Communication costs will vary for each dyad depending on the locations involved and on the quality of the communication tools.
- Owing to large number of people involved, effective communication and collaboration tools are critical.
- Clarification costs are lower with effective asynchronous collaboration tools like configuration management systems.
- Besides change management, these tools can be used to describe issues and requirements, record errors, repair miscommunication, etc., all of which reduce P_U .
- Clarification costs are lower with effective asynchronous collaboration tools like configuration management systems.
- Besides change management, these tools can be used to describe issues and requirements, record errors, repair miscommunication, etc., all of which reduce P_U .
- Rework costs are lower with a lower P_U due to effective collaboration tools.
- Rework costs can be reduced further by incurring clarification costs early in the task to reduce R_w .
- On the other hand, if C_p is low for the producer's site, but C_d is high for the requestor, it may pay off to risk the possibility of rework to reduce clarification costs.

1 a sequence of communication events rather than
2 a simple request and acknowledgement. We also
3 assumed that actors communicate synchronously
4 during overlapping periods and asynchronously
5 otherwise. In reality, actors who wish to communi-
6 cate during nonoverlapping hours have the choice
7 of communicating asynchronously or of waiting
8 until the overlapping period and then communicat-
9 ing synchronously, which can be modeled with a
10 delay cost rate function dependent on the priority
11 of the task that takes into account the additional
12 cost of waiting against the expected gain in mes-
13 sage clarity. We further assumed that face-to-face
14 communication occurs instantaneously and at no
15 cost. In reality, face-to-face meetings and preparing
16 task-request messages can consume substantial pro-
17 ductive time. This can be modeled by incorporating
18 further time delays based on the task complexity,
19 which will affect the message preparation time and
20 the number of meeting participants, which creates
21 production blocking (i.e. only one person can talk
22 at a time). Nevertheless, the practical, theoretical,
23 and modeling perspectives discussed in this paper
24 underscore the differences between collaborations
25 in software development that are purely separated
26 by geographic distance from those that are also
27 separated by time differences. We now discuss the
28 overarching issues that emerged in this study.

5.1. Time Separation Means Reduced Overlap in Work Hours, not Time-zone Differences

33 Time separation boils down to the amount of
34 overlapping work time in which the team can
35 interact synchronously. •This work-time overlap,
36 not just because of time zones but also because of
37 factors such as nonoverlapping weekend days and
38 holidays, shifts, and different working schedules,
39 can be reduced. An important feature of our model
40 is that it purposely omits any reference to time zones
41 and focuses more specifically on time separation.
42 We represent this time separation in reverse, using
43 a work-time overlap index (O'Leary and Cummings
44 2002), which can be used to model any form of time
45 separation among team members.

5.2. Time Separation Leads Most Teams to Change their Work Norms

50 Specifically, individuals and teams adjust and shift
51 their work hours to change work-time overlaps

to suit their needs. Our model contains five cost
52 components: production, communication, delay,
53 clarification, and *rework costs*. If a given time-
54 separation configuration is not cost-effective (e.g.
55 due to time zones), rational actors will make
56 decisions to change work schedules of some or
57 all of its members to either increase time overlaps
58 to reduce clarification and *rework costs* (e.g. create
59 liaison roles) or reduce time overlap to reduce *delay*
60 *costs* (e.g. shift work, *follow-the-sun*), provided that
61 the timing of task requests can be programmed
62 optimally.

5.3. Time Separation's Impact on Team Interaction Leads to Choices of Synchronous or Asynchronous Communication in a Number of Ways

In general, when team members are only sepa-
71 rated by geographic distance, they have a choice
72 of interaction mode. We recognize that there are
73 times when one mode may be more effective than
74 the other (e.g. send e-mail when a person is away
75 from the desk), but because work hours fully over-
76 lap, there are more communication options. Teams
77 separated by time have fewer choices on how
78 to interact, and they often need to make choices
79 between synchronous and asynchronous interac-
80 tion tactics. Our model can be simulated under
81 a number of different assumptions. For example,
82 one simplifying assumption we made in a recent
83 study (Espinosa *et al.* 2003) was that actors commu-
84 nicate synchronously during work-overlap hours
85 and asynchronously otherwise. This assumption
86 can be relaxed to model more realistic conditions.
87 For example, if we assume that actors make rational
88 choices, then an actor may either: (a) communicate
89 asynchronously (e.g. e-mail) during overlapping
90 hours because the message is very technical and
91 it is better explained in writing, thus reducing
92 the probability of unclear messages and reduc-
93 ing *vulnerability costs*; or (b) defer communication
94 until hours overlap to communicate synchronously
95 to discuss more equivocal matters over a richer
96 medium (e.g. videoconference), thus reducing the
97 probability of unclear messages and reducing *vul-*
98 *nerability costs*. These rational choices would involve
99 actors making decisions on the basis of probabilities
100 and trade-offs between *delay costs* and *vulnerability*
101 *costs*. 102

1 **5.4. Distance Separation is Symmetric – i.e.**
2 **Distance (A,B) = Distance (B,A) – while Time**
3 **Separation is Asymmetric**

4 The type of overlap (i.e. at the beginning or end
5 of one's workday) makes a difference in time-
6 separated work but is not an issue in purely
7 geographically dispersed contexts. While making
8 task requests later in the day diminishes the benefits
9 of overlap time, making late requests are somewhat
10 more beneficial when the work-overlap time occurs
11 at the end of one's day. Planning interactions
12 and task work needs to take into account, when
13 overlapping work hours occur. The main effect of
14 this asymmetry is that the timing of a task request (or
15 a task completion acknowledgement) really matters
16 in time-separated contexts, whereas the timing does
17 not matter in distance-only contexts. The simplified
18 cost formulas we have presented in this article don't
19 incorporate this asymmetry directly. However, the
20 computation of time delay (T_d), which affects two
21 of the four coordination cost components (i.e. delay
22 and clarification), is affected by this asymmetry.
23 The effects of this asymmetry surfaced visibly in the
24 model evaluations we conducted with simulated
25 data (Espinosa *et al.* 2003, Espinosa and Carmel
26 2004).

27
28
29 **5.5. In Time-separated Contexts, the Type of**
30 **Time Separation Configuration Makes a**
31 **Difference**

32 While different distance separation arrangements
33 matter in collaboration, teams that are not separated
34 by time can still use a variety of synchronous com-
35 munication tools (e.g. voiceconference, videocon-
36 ference) and initiate instant interactions as needed.
37 On the other hand, the more complex the time-
38 separation configuration of a team, the more diffi-
39 cult it becomes to initiate or plan team interactions.
40 Our model makes evident the cost trade-offs of dif-
41 ferent time-separation conditions and the manner
42 in which they are affected by the nature of the task
43 and the quality of the communication media avail-
44 able. Equivocal tasks (e.g. requirements engineering
45 and design) that require more frequent interaction
46 over rich media are more effective in work configu-
47 rations with substantial work-time overlap among
48 members so that *vulnerability costs* may be reduced
49 (i.e. the probability of unclear messages is lower).
50 On the other hand, less equivocal tasks (structured
51 tasks, such as testing, and error fixing) may be

better suited for *follow-the-sun* configurations that
52 contain less overlapping work hours so that *delay* 53
costs are reduced (i.e. assuming that the timing of 54
task requests can be programmed optimally). 55

56
57
58 **5.6. The Time Perspective Among Collaborators**
59 **is the Same When they are Only Separated by**
60 **Geographic Distance, but not When they are**
61 **Separated by Time**

62 When work times fully overlap, the time it takes
63 to complete a task by someone else is equal to the
64 time one has to wait for that task to be completed
65 (i.e. $T_t = T_d$). However, because of the asymmetric
66 nature of time separation, when work hours do
67 not overlap, the time it takes for one member to
68 complete a task only affects the *Requestor's delay costs*
69 if the waiting time occurs during the overlapping
70 hours. If the work takes place during the *Requestor's*
71 off-work hours, then that time does not affect
72 *delay costs*. Conversely, if the task is requested
73 before the *Producer* arrives to work, this produces
74 extra delay in the *Requestor's* time, which is not
75 perceptible to the *Producer*. This difference in time
76 perspectives is often a source of misunderstanding
77 and a lack of sensitivity to the other site's time
78 constraints. This effect is captured in the model
79 formulas in the computation of delay times (T_d),
80 which is measured from the *Producer's* perspective.
81 Therefore, the timing of task activities is a critical
82 issue in time-separated conditions but not when
83 separated by distance only.

84
85
86 **5.7. Vulnerability Costs Increase with Time**
87 **Separation**

88 Vulnerability costs – i.e. clarification plus rework
89 costs – increase with time separation because of
90 two reasons: (a) the timing of the interaction is
91 affected by time differences, which is evident in
92 our model by the interaction of the time vari-
93 ables (T_t and T_d). Naturally, if miscommunication
94 occurs frequently, time separation makes it diffi-
95 cult to interact frequently and spontaneously, thus
96 introducing further delay; and (b) the choice of com-
97 munication media is limited to the tactic employed
98 (i.e. synchronous or asynchronous). In some cases,
99 suboptimal communication media may be chosen,
100 thus increasing the chance of miscommunication.
101 *Vulnerability costs* are also affected by whether the
102 team is colocated (or not) and by the amount of 102

1 overlapping work time. It is not the same to have
 2 80% overlapping work time between two sites as it
 3 is to have only 10%. The narrower the window for
 4 synchronous interaction, the fewer choices the team
 5 will have for synchronous communication tactics.
 6 This is also evident in our model in which the prob-
 7 ability of unclear messages P_u is affected by the
 8 quality of the communication medium used and by
 9 the amount of work-time overlap available to repair
 10 miscommunication in a timely manner.

11 In conclusion, time separation has profound
 12 effects on the software process. Regardless of
 13 the software development method employed (e.g.
 14 waterfall, incremental, Unified Process, Extreme
 15 Programming), coordination is critical to the man-
 16 agement of the software process, particularly, as
 17 the software size and the project team get larger
 18 (Brooks 1995). And, because software is a com-
 19 plex and equivocal task with intricate dependencies
 20 among multiple activities, communication is the key
 21 to accomplish coordination (March and Simon 1958,
 22 Thompson 1967) and to manage the software pro-
 23 cess dependencies effectively (Espinosa *et al.* 2001).
 24 The software process not only involves many devel-
 25 opers making decisions and carrying out tasks
 26 individually but also involves subsequent coordina-
 27 tion, which is necessary to integrate this individual
 28 work, resolve mutual constraints, and manage task
 29 dependencies. This coordination is not only neces-
 30 sary to produce software that meets requirements
 31 in a timely manner but it is also one of the most
 32 difficult and pervasive problems in the software
 33 process (Herbsleb and Mockus 2003). Time sep-
 34 aration not only affects the timing of planned
 35 communication but it also affects team members'
 36 ability to interact frequently, informally, and spon-
 37 taneously, which has an impact on the coordination
 38 of task activities in the software process (Kraut and
 39 Streeter 1995). In closing, we highlight our main
 40 argument that same-time and different-time col-
 41 laboration contexts present different challenges for
 42 practice and research. Much of the research in global
 43 and geographically distributed teams does not dis-
 44 tinguish distance separation from time separation.
 45 To avoid confounds, we suggest that future empiri-
 46 cal research in global software teams needs to either
 47 control for time differences within teams or be con-
 48 ducted with teams that are not separated by time.
 49 We expand on this theme by delineating the number
 50 of dyad interaction patterns that exist in time sep-
 51 aration versus same-time teams. While in same-time

contexts, there are only two possible collaboration 52
 modes, colocated or distributed; in different-time 53
 contexts, there are 16 possible collaboration modes 54
 depending on whether 55

- the collaboration is either colocated or dis- 56
 tributed (2x); 57
- a member makes a task request during or outside 58
 the overlapping work hours (2x); 59
- the other member completes the task during or 60
 outside the overlapping work hours (2x); and 61
- the overlap occurs at the beginning or at the end 62
 of one's workday (2x). 63

This underscores the difference with pure 65
 distance-separated contexts, where time-related 66
 variables do not have a strong influence on coordi- 67
 nation and *vulnerability costs*. 68

6. FUTURE RESEARCH 70

Having merged together theory, exploratory field 72
 research, and a basic model, we have defined a 73
 conceptual foundation for deeper research into 74
 time-separated coordination. We identify a number 75
 of research approaches for further study, which we 76
 discuss below: 77

6.1. Simulation Research 80

While we have provided preliminary validation of 81
 our model, our approach has been simple, using 82
 randomly drawn values from expected statistical 83
 distributions of variables; we believe that more 84
 formal and thorough simulation studies can pro- 85
 vide further insights. Further simulation can both 86
 expand the model and relax some of our assump- 87
 tions. 88

6.2. Experimental Research 90

Experimental studies can be used to hypothesize 92
 and test fine-grained aspects of our model and 93
 time-separated work in general. An experimental 94
 approach is likely to be designed around several 95
 time-overlap conditions, such as 0, 20, 50, 80 and 96
 100%. Other variables may also be manipulated: 97
 task completion time (Tt) relative to the length of the 98
 workday; daily cost of delay (Cd); communication 99
 medium quality (i.e. affecting the probability of 100
 unclear messages); and amount of rework needed 101
 (Rw). 102

AQ10

1 **6.3.. Field Research**

2 We see two steps in doing field work. The first
3 is to continue and expand exploratory studies,
4 interviewing, and surveying software developers
5 in multiple organizations to: (a) identify effective
6 design of work configurations in time-separated
7 conditions; (b) develop a deeper understanding of
8 the key issues that developers face in time-separated
9 work arrangements; and (c) learn about how these
10 teams cope with the challenges of time separation.
11 Results of such a study can be used to refine our
12 model. Second, we propose a case-study design at
13 a single organization to explore relative *coordination*
14 *costs* in different time-distance configurations. The
15 organization may have either a single large team
16 with members in multiple locations across different
17 time zones or a number of smaller teams configured
18 in a variety of configurations: (a) colocated team
19 (i.e. the control condition); (b) dispersed sites across
20 the same time zone; and (c) dispersed sites across
21 different time zones. Such research can make use
22 of three groups of data: interviews, survey, and
23 system-derived data, possibly generated from the
24 configuration management system.
